ABSTRACT

The study presents comparative global evidence on the transformation of economic growth to poverty reduction in developing countries, with emphasis on the role of income inequality. The focus is on the period since the early-mid-1990s when growth in these countries as a group has been relatively strong, surpassing that of the advanced economies. Both regional and country-specific data are analyzed for the \$1.25 and \$2.50-level poverty headcount ratios using World Bank Povcalnet data. The study finds that *on average* income growth has been the major driving force behind both the declines and increases in poverty. The study, however, documents substantial regional and country differences that are masked by this ‘average’ dominant-growth story. While in the majority of countries, growth was the major factor behind falling or increasing poverty, inequality, nevertheless, played the crucial role in poverty behavior in a large number of countries. And, even in those countries where growth has been the main driver of poverty-reduction, further progress could have occurred under relatively favorable income distribution. For more efficient policymaking, therefore, idiosyncratic attributes of countries should be emphasized. In general, high initial levels of inequality limit the effectiveness of growth in reducing poverty while growing inequality increases poverty directly for a given level of growth. It would seem judicious, therefore, to accord special attention to reducing inequality in certain countries where income distribution is especially unfavorable. Unfortunately, the present study also points to the limited effects of growth and inequality-reducing policies in low-income countries.

1. Introduction

The last two decades have witnessed the economic emergence of developing countries, which have as a group exhibited relatively high GDP growth rates, in excess of those prevailing in the developed countries. The gap has been particularly

apparent since the middle 1990s. Much of this 'shifting wealth' has, furthermore, been translated to increasing human development, such as poverty reduction. Global poverty has fallen substantially, with a major portion of the decline attributable to China. Even when China is omitted from the sample, poverty reduction is still considerable (Chen and Ravallion, 2008). This record of achievement has, however, been far from uniform. A number of countries have experienced little poverty reduction or even increasing poverty. Part of the disappointing performance might be attributable to dismal growth, as experienced by many African countries in the 1980s and early 1990s. High income inequality, evident in several Latin American countries historically, could also prove to be a major culprit.

In explaining how the substantial growth in developing countries may have contributed to improving human development, particularly poverty reduction, it is crucial to understand the role of (income) inequality in the growth-poverty nexus (e.g., Bourguignon, 2003; Epaulard, 2003; Fosu, 2009; Kalwij and Verschoor, 2007; Ravallion, 1997; World Bank, 2006a, 2006b). That inequality influences growth's transformation to poverty reduction, furthermore, suggests that even with the same level of growth, countries faced different likelihoods of attaining goal 1 of the Millennium Development Goals (MDG1) of halving poverty by 2015, instead of the generally accepted 7 percent average annual GDP growth. There would indeed be country-specific thresholds depending on the distribution of income inequality across countries (ibid.). The current sustainable development goal 1 (SDG1) of eradicating poverty by 2030 would similarly entail country-level growth requirements.

Based on available internationally comparable global panel data from the World Bank's Povcalnet (see Chen and Ravallion, 2008; World Bank, 2007, 2008, 2009a), the present paper presents regional and comparable country evidence on poverty reduction. It explores the extent to which the recent generally strong growth of developing countries may have been translated into poverty reduction. In particular, the paper provides country estimates of the relative contributions of inequality and income to the inter-temporal behavior of poverty for a large global sample of developing countries, and decomposes the progress on poverty into income and inequality changes, during the relatively recent period when developing countries have experienced strong growth. The paper finds that while *on average* income growth has been the main factor behind poverty reduction globally, the role of income distribution has been critical for many countries.¹

While the present results support the general view in the literature that growth is the main driver of the recent decline in poverty (e.g., Dollar and Kraay, 2002), it nonetheless suggests a prominent role for income distribution. Indeed, for a number of countries, it is the main factor behind the progress, or lack thereof, on poverty. By providing country-specific evidence on the relative roles of income and inequality, the current findings should inform the policy debate on especially the sustainable development goal 1 (SDG1), as well as provide a retrospective perspective on its MDG1 predecessor. More generally, though, the paper's country-specific results present a useful comparative analysis that transcends the usual cross-country and regional analyses. After all, the challenge is at the country level where policymakers must seek the optimal mix of emphases on economic growth versus inequality, in order to maximize poverty reduction. The findings of the current study should, therefore, prove useful for both focused research and policymaking not only regionally but especially at the country level.

The paper is structured as follows. First, it presents regional and country comparisons of progress on both growth and poverty, with emphasis on the recent period since the early-to-mid 1990s (Section 2). The main objective in Section 2 is to glean, based on qualitative analysis, the comparative abilities of developing countries and, hence, regions to transform growth to poverty reduction. Second, the paper employs the 'identity model' to estimate the poverty equation involving changes in income and inequality as well as the poverty line relative to mean income, and estimates the income and inequality elasticities of poverty (Section 3). Third, employing these elasticities, poverty changes during the more recent period since the early-to-mid 1990s are decomposed for each sample country into contributions by income and inequality changes (Section 4). Fourth, Section 5 presents several illustrative comparative country simulations on poverty progress, based on various growth and inequality scenarios. Finally, Section 6 summarizes the findings of the paper, with implications for research and policy.

2. Comparative trends in growth and poverty

2.1. Regional GDP growth and poverty reduction, 1981–1995 vs. 1996–2005

We present in this section the regional trends in GDP growth and poverty reduction for the periods: 1981–1995 and 1996–2005. The sample period begins in 1981 when much of the globally comparable poverty data became available. These two sub-periods are chosen to reflect the dichotomy of the growth pattern of developing countries, which exhibit relatively strong growth in the latter period (Fig. 1).²

Table 1 presents the 1981–1995 and 1996–2005 regional averages of per capita GDP growth and annualized growth rates of the headcount ratio based on the \$1 (\$1.25) and \$2 (\$2.50) standards.³ The six regions are: East Asia and the Pacific (EAP),

¹ Fosu (2015) presents similar findings for sub-Saharan Africa.

² Note, though, that as Fig. 1 also shows, there was a similar increasing gap from the 1960s until the mid-1970s, but then a decline until the early-mid-1990s when the more recent acceleration began.

³ The annualized growth rates are calculated as the logarithmic differences between the poverty rates between 1996 and 2005, divided by the frequency of the intervening years.

Fig. 1. Trend in developing-developed countries' GDP growth gap. *Notes:* LMY and HIC are 'low & middle-income' and 'high-income' countries, respectively. LMY-HIC is the GDP growth of LMY less GDP growth of HIC. The solid line depicts the actual values of (LMY-HIC) and the dotted line is the fitted values from a 3rd-order polynomial time trend. (Data source: World Bank WDI Online, 2009b.)

Table 1

Per capita GDP growth vs. poverty reduction by region, 1981–2005.

Region/variable – period	P.C GDP growth		\$1.25 P ₀ growth		\$2.50 P ₀ growth	
	1981–1995	1996–2005	1981–1996	1996–2005	1981–1996	1996–2005
East Asia and Pacific (EAP)	6.894	6.355	–5.126	–8.481	–1.616	–4.331
Eastern Europe and Central Asia (EECA)	–3.434	4.138	6.769	–2.594	1.229	–3.911
Latin America and Caribbean (LAC)	0.140	1.394	–1.083	–3.176	–0.605	–2.538
Middle East and North Africa (MENA)	0.713	2.309	–4.347	–1.445	–1.215	–1.484
South Asia (SAS)	3.208	4.143	–1.548	–1.710	–0.296	–0.530
Sub-Saharan Africa (SSA)	–1.009	1.293	0.644	–1.597	0.270	–0.517

Notes: All figures are annual averages and are in percent. P.C. GDP growth rates are calculated from World Bank (2009b) as averages of annual regional values. P₀ is the headcount ratio and its growth rate is annualized: calculated as the logarithmic difference ($d \log P_0$) of ending-year value and beginning-year value, divided by the number of years between the two years, $\times 100$ percent (data source: World Bank, 2009a).

Eastern Europe and Central Asia (EECA), Latin America and the Caribbean (LAC), Middle East and North Africa (MENA), South Asia (SAS), and sub-Saharan Africa (SSA).

We note, first, that EAP registered spectacular GDP growth per capita, resulting in substantial poverty reductions over both sub-periods. Second, for EECA, the large per-capita GDP decline in the first period seems to account for the considerable increase in poverty during that period; conversely, a substantial decrease in the poverty rate during the latter period accompanied that period's strong economic growth. Third, considerable poverty reduction seems to have resulted from the rather modest GDP growth in LAC, especially during the latter period. Fourth, the moderate GDP growth of MENA was transformed to appreciable poverty declines during the early sub-period, but the stronger growth in the latter period resulted in only modest poverty reduction.

In the case of SAS, the substantial GDP growths in both sub-periods appear to have been translated to only moderate poverty reduction. Finally, for SSA the per capita GDP decline in the first period seems to account for the poverty rise during that period; conversely, poverty reduction in the latter period appears to have resulted from appreciable economic growth that period. Interestingly, the rates of poverty decline since the mid-1990s were about the same between the SSA and SAS, despite the latter's much stronger GDP growth.

The above observations point to considerable regional differences in the responsiveness of poverty to GDP growth. For example, the finding of SAS's relatively modest poverty reduction despite strong GDP growth in both sub-periods suggests three possible explanations: (1) GDP growth did not sufficiently reflect actual income growth⁴; (2) the responsiveness of poverty to income growth was weak; or (3) inequality may have increased. In contrast, the substantial poverty declines in EAP seem as expected, given the region's spectacular growth. Understanding such inter-regional discrepancies in the transformation of GDP growth to poverty reduction, however, would require a deeper analysis of the poverty function, which is undertaken in a subsequent section.

⁴ 'Income' refers to the PPP-adjusted income from World Bank (2009a, 2009b), derived from per capita consumption from household surveys or the interpolated private consumption from national accounts (Chen and Ravallion, 2008).

2.2. Poverty trends by region and for the 'emerging giants'

To shed further light on the trends in the global picture of poverty, Table 2 presents in greater detail the regional evidence corresponding to the two poverty standards. In addition to the six regions, evidence is provided for the two most populous countries and 'emerging giants', China and India. For the six regions, the table presents \$1.25 and \$2.50-standard headcount ratios for 1981, 1996 and 2005; these years span the 1981–2007 period for which country data are sufficiently reliable to produce the regional averages (World Bank, 2009a).⁵ Table 2 also reports statistics for these same years in the case of China. Evidence is presented for both rural and urban sectors as well as for the overall economy, computed as a population-weighted mean of the two sectors. For India, the years are 1983, 1994 and 2005, since these are the specific years spanning the 1981–2007 period for which relatively reliable survey data are available.

Consider first the poverty trends at the \$1.25 standard. In 2005, poverty was highest in SSA and lowest in MENA and EECA. Between 1981 and 2005, it declined for all regions except EECA, where the initial value was rather small to begin with. Among the remaining regions, in percent (logarithmic change) terms, the greatest reduction in poverty is observed for EAP, followed by MENA, LAC, SAS and SSA, in that order. There are differences across time, though. During 1981–1996, for example, poverty increased for EECA and SSA but declined for all other regions. In 1996–2005, however, poverty decreased for all regions. The largest decline (in percent terms) was in EAP, followed by LAC and EECA, then by SAS, SSA and MENA.

⁵ Regional poverty data are available for other years over 1981–2007 as well, but we have opted to interpolate between the selected years for the growth rates, in order to provide comparable regional analysis for the two sub-periods.

Moreover, the fall in poverty was faster in the latter period in all regions except MENA, which had a low level of poverty to start with. Thus, for all practical purposes, the last decade has witnessed reductions in the poverty rate, at least at the \$1.25 level, for all regions of the world.

In terms of the 'emerging giants', China's poverty rate at the \$1.25 level fell in both sub-periods but faster in the second period for both the urban and rural sectors. India's poverty also fell in both periods but more rapidly in the second period for only the rural sector, though the decline was sufficient for translating into a faster poverty reduction for the whole economy. China's poverty also fell much faster than India's in both sub-periods, overall and by sector. Furthermore, poverty in China decreased substantially more in the urban than in the rural sector, further exacerbating the urban–rural difference over time. For India, the decline was faster in the urban than in the rural area during the first period, but the reverse was the case in the latter period. It is also noteworthy that poverty fell less in India than in the SAS region generally for each of the sub-periods. Moreover, poverty reduction in India during the latter period was about the same as that in SSA, despite the fact that India's GDP growth was much faster than SSA's.

We now consider poverty trends at the \$2.50 standard. The observations are generally similar to those above for the \$1.25, though there are appreciable differences as well. During the entire 1981–2005 period, poverty declined the most in EAP and the least in SSA. It rose during 1981–1996 for EECA and SSA but fell in all regions during 1996–2005. The lowest declines in the latter period were in SAS and SSA (about equally), though the poverty rate in 2005 was highest in SAS, not in SSA, contrary to the finding at the \$1.25 standard.

Considering the two emerging giants, again, poverty at the \$2.50 standard fell faster in the second period for both China and India. Furthermore, China's poverty declined much faster than India's during both sub-periods. The poverty rate at this standard for China also fell more rapidly in urban than in rural areas in both periods. India's poverty similarly fell faster in the urban area than in the rural sector in both periods, in contrast with the above observation at the \$1.25 level where the decline was faster in the rural area in the latter period. Furthermore, in 2005 India's poverty at the \$2.50 standard was slightly higher than that in SAS as a whole and was about 5 percentage points higher than that in SSA. Finally, India's poverty declined slightly less than that of either SAS or SSA during the latter period.

2.3. Current poverty rates: global evidence by country

To provide global country comparisons, 80 developing countries that have sufficient data for the early-mid-1990s and also for the 2000s are selected.⁶ We first examine the distributions of their poverty rates since the early-mid 1990s when developing countries' growth generally has accelerated. This is done in Table 3. We find that at the \$1.25 standard, the poverty rate ranges from 0.0 percent in Belarus (2005), Estonia (2005) and Latvia (2005) to 88.5 percent in Tanzania (2000), with a median of 17.9 percent.

With respect to the emerging giants, China's urban and rural poverty rates at the \$1.25 level are 1.7 percent and 26.1 percent, respectively, with the latter above the 'global' median of 17.9 percent. Thus, 'extreme' poverty has become essentially a rural phenomenon in China. In contrast, at 43.8 percent and 36.2 percent, respectively, India's rural and urban poverty rates are well above the 'global' median. It appears then that India's strong GDP growth in the more recent period may not have similarly reduced poverty.

Similar observations hold at the \$2.50 poverty standard. Here the range is from 0.9 percent in Belarus to 98.2 percent in Tanzania, with a median of 47.7 percent. For the emerging giants, China's respective urban and rural poverty rates are 17.8 percent and 34.8 percent, which are both below the 'global' median. In contrast, at 77.3 percent and 89.0 percent, respectively, India's urban and rural poverty rates are both substantially above the 'global' median, as in the case at the \$1.25 standard.

2.4. Growth vs. poverty reduction by country, early-mid-1990s to present⁷

For the global sample of 80 countries Table 4.1 presents, over the early-mid-1990s to the present, data on per capita GDP and income growths, and on the growth of poverty at both the \$1.25 and \$2.50 standards. Also reported in the table are data on the growth of inequality, represented by the Gini coefficient. The goal here is to assess how GDP growth or income growth may have been translated to poverty reduction at the country level.

For many of these countries, reasonably strong GDP growth seems to have resulted in substantial poverty reduction: (e.g., Azerbaijan, Brazil, Cameroon, Chile, China, Costa Rica, Ecuador, Egypt, El Salvador, Estonia, Ghana, Honduras, Indonesia, Jamaica, Jordan, Kenya, Latvia, Mali, Mauritania, Moldova, Pakistan, Poland, Romania, Russian Federation, Senegal, Sri Lanka,

⁶ The selection criterion is intended to ensure that we can also consistently and comparably analyze changes in the poverty rate over time for the same set of countries. The wider interval of early-mid-1990s is used as the starting point in order to include as many countries as possible in the sample, for a number of the countries had data in the early but not in the mid-1990s, and vice versa. Note that the average over the starting period could not be used due to the need for annualizing. The closest year to 1996 with data within 1990–1996 is selected as the starting year, because more of the countries have data for the mid-1990s but not for the earlier 1990s. For each country, the latest year in the 21st century for which data were available at the time of the initial study constitutes the 'present' period for the analysis.

⁷ By 'present' it is meant the year when the data employed for the analysis ended in about the mid or late-2000s for most sample countries. This definition is retained for the rest of the paper.

Table 3

Notes: These are the 80 countries with data for 2000 or onward, as well as data in the early-mid-1990s (1990–1996); see the text for details of the selection criteria. P_0 is the headcount ratio. Year indicated in parentheses is the latest year for which there is data. (Data source: World Bank, 2009a.)

Swaziland, Thailand, Tunisia, Uganda, Ukraine, and Vietnam). In several other countries, however, strong GDP growth was accompanied by only modest poverty reduction, either because the growth did not result in similar increases in income or because inequality increased to thwart the transformation process (e.g., Albania, Georgia, India, Iran, Kyrgyz Republic, Mongolia, and Yemen).

To better illustrate this poverty–growth linkage by country, we order by deciles the 80 sample countries with respect to their GDP and income per capita growth rates, on the one hand, and the poverty rates, on the other. The results are summarized in Table 4.2 as country ‘poverty transformation efficiency’ (PTE) vectors; the first two coordinates indicate the decile rankings of per-capita GDP and income growths, respectively, while the last two coordinates indicate the respective reductions in the \$1.25 and \$2.50-level poverty rates.⁸ For example, the (2, 8, 10, 9) vector for Albania means that the country was in the 2nd and 8th top deciles for per-capita GDP and income growths, respectively, but in the 10th and 9th top deciles of poverty reduction at the \$1.25 and \$2.50 standards, respectively. Hence, Albania performs rather poorly in transforming GDP growth to poverty reduction, explained mainly by the weak translation of GDP to income growth. Actually, Georgia’s PTE vector of (1, 10, 10, 10) demonstrates this phenomenon too well. The country’s per-capita GDP growth places it in the top decile; however, Georgia performs among the worst decile on both income growth and poverty reduction.

Conversely, according to the PTE vectors in Table 4.2, there are many countries where income has actually outperformed GDP, including: Cameroon, CAR, Costa Rica, Cote d’Ivoire, Ecuador, Ghana, Honduras, Indonesia, Jamaica, Kenya, Mexico, Nepal, Pakistan, Romania, Senegal, Swaziland, and Venezuela. Given, further, that income is generally a better reflector of poverty than GDP is, GDP growth would underestimate poverty performance in these countries. And, there are those countries which performed quite well on all the four coordinates and have, thus, translated strong GDP growth to substantial declines in poverty, including: Azerbaijan, Jamaica, Latvia, Mexico, Poland, the Russian Federation, Tunisia, Ukraine and Venezuela.

Turning to the emerging giants, India’s respective rural and urban PTE vectors of (2, 7, 7, 7) and (2, 7, 8, 8) imply that the country’s stellar performance on GDP growth was poorly translated to income growth; however, India’s record of poverty reduction fairly matches its income performance.⁹ Apparently, the main culprit is the minimal increase in income despite the strong GDP growth (Table 4.1). In contrast, China’s rural and urban PTE vectors are (1, 2, 4, 4) and (1, 1, 3, 2), respectively. Hence, its GDP growth appears to be a good indicator of income performance; nonetheless, according to these vectors, the country’s performance on poverty, relative to its economic growth, seems somewhat below par.

⁸ A lower-number decile for the GDP or income growth indicates a grouping of higher-growth countries, and a lower-number decile for the poverty rates indicates a grouping of larger poverty-reduction countries.

⁹ India’s per-capita GDP grew at a stellar annual average rate of nearly 5.0 percent, and yet the average annual rate of poverty reduction was only 1.6 percent and 1.1 percent for the rural and urban sectors, respectively. Although part of the weak performance on poverty may be due to increases in inequality (Table 4.1), the weak GDP-income linkage appears to be the main culprit, as the PTE vectors amply imply (Table 4.2).

Notes: Data are annual or annualized averages and in %. Per-capita GDP growth rates are the 1995–2005 means of annual values from World Bank (2009b). P_0 is the headcount ratio. Growth rates of P_0 , Mean Income and Gini (measuring inequality) are calculated as the log-differences using latest-year and start-year (most recent in 1990–1996) values, divided by the number of years between the two periods, $\times 100$ percent (source: World Bank, 2009a); see text for further details. Note that for Belarus, Estonia and Latvia the latest value for \$1.25-standard P_0 is reported as 0; for the purpose of computing the growth rate, this value has been approximated by 0.001. This approximation suggests that the corresponding estimates should be viewed with some caution.

^a 'Present' is the latest year available in the database for each country, that is, in about the mid or late-2000s. This definition is retained for the rest of the tables.

3. Transforming growth to poverty reduction—a quantitative assessment

3.1. Existing literature and estimating equation

The above discussion suggests that differences in regional or country experiences in poverty reduction may be attributable in considerable part to disparities in economic growth. Indeed, according to a strand of the literature, growth is the most powerful, if not the only, agent for poverty-reduction (e.g., Dollar and Kraay, 2002). Nonetheless, as we have also observed, there are many countries where GDP or income growth may not adequately be translated to poverty reduction.

As alluded to in the introduction, however, an increasing number of studies have shown that inequality may play a crucial role in the transformation of growth to poverty reduction (e.g., Adams, 2004; Bourguignon, 2003; Easterly, 2000; Epaulard, 2003; Fosu, 2009; Kalwij and Verschoor, 2007; Ravallion, 1997). In general, less initial inequality would imply a greater (absolute) value of the income elasticity, ceteris paribus, so that a larger amount of poverty decline would accompany a unit of growth.¹⁰

We explore herein the global evidence on the transformation of income growth, as well as changes in inequality, to poverty reduction, with inequality serving as an important intermediation factor. Different types of models have been used to capture this relationship. One type involves separate estimation of the poverty equation for different Gini coefficients (e.g., Adams, 2004). Closely related to this specification is a model that includes an interaction of growth with initial inequality (e.g., Easterly, 2000; Fosu, 2009; Ravallion, 1997). Other models also symmetrically include an interactive term involving (logarithmic) income and (logarithmic) Gini coefficient (e.g., Fosu, 2008, 2010a, 2010b, 2010c), so that the implied elasticity would entail the levels (rather than growths) of income and inequality.

For the current study, we opt for the relatively fully specified poverty equation, whose derivation is guided by the assumption that income is log-normally distributed (Bourguignon, 2003; Epaulard, 2003; Fosu, 2009; Kalwij and Verschoor, 2007)¹¹:

$$p = b_1 + b_2y + b_3yG^l + b_4y(Z/Y) + b_5g + b_6gG^l + b_7g(Z/Y) + b_8G^l + b_9Z/Y \quad (1)$$

¹⁰ Note, though, that a perverse outcome is conceivable, since redistributing from the non-poor to the poor in a very low-income economy could actually increase the poverty rate, so that less inequality might engender greater poverty in such countries; see Fosu (2010a, 2010b, 2010c), for instance, for an elaboration of this point.

¹¹ Indeed, the basic relationship is an identity (Bourguignon, 2003), which renders the specification potentially the most comprehensive. For derivation details, see Bourguignon (2003), Epaulard (2003), and Kalwij and Verschoor (2007).

Notes: 'Efficiency Vector' has the deciles ranks as coordinates. For example Albania's Efficiency Vector of (2, 8, 10, 9) means that the country's deciles ranks are 2, 8, 10 and 9, respectively, on per-capita GDP growth, per-capita income growth, poverty reduction at the \$1.25 standard and poverty reduction at the \$2.50 standard.

where p is the growth in the poverty rate, y is income growth, g is growth in the Gini coefficient, G^I is the initial Gini coefficient (expressed in logarithm), Z/Y is the ratio of the poverty line Z to income Y (expressed in logarithm), and b_j ($j=1, 2, \dots, 9$) are the respective coefficients to be estimated.

The sign of b_2 is anticipated to be negative, so that an increase in income growth should reduce poverty growth, ceteris paribus. In contrast, b_3 is expected to be positive, for a higher level of initial inequality would decrease the rate at which growth acceleration is transformed to poverty reduction. The sign of b_4 should be positive as well, consistent with the hypothesis, based on the lognormal income distribution, that a larger income (relative to the poverty line) would have associated with it a higher income-growth elasticity.¹² (Bourguignon, 2003; Epaulard, 2003; Fosu, 2009; Kalwij and Verschoor, 2007).

The sign of b_5 is theoretically positive, for a worsening income distribution is expected to increase poverty, ceteris paribus. In contrast, b_6 cannot generally be signed; however, it would be negative if there was diminishing poverty-increasing effect of rising inequality. The sign of b_7 would also be negative, as in a relatively low-income economy (high Z/Y) improving income distribution (lowering g) might exacerbate poverty by increasing the likelihood of more people falling into poverty. Finally, b_8 and b_9 are likely to be positive; rising initial inequality or increasing poverty line relative to income

¹² We shall ignore the sign and adopt the convention of referring to the income elasticity by its magnitude.

should, *ceteris paribus*, exacerbate poverty, respectively, though these coefficients do not affect the income or inequality elasticity of poverty (Bourguignon 2003; Epaulard, 2003; Fosu, 2009; Kalwij and Verschoor, 2007).

From Eq. (1), the respective income and inequality elasticities are obtained as

$$E_y = b_2 + b_3 G^I + b_4 Z/Y \quad (2)$$

$$E_g = b_5 + b_6 G^I + b_7 Z/Y \quad (3)$$

Hence, given the above expected signs, E_y and E_g are generally anticipated to be negative and positive, respectively, so that increasing income growth should reduce the growth of poverty, while inequality acceleration would exacerbate poverty increases. It is conceivable, though, that perverse signs of the elasticities could occur. For example, in a highly unequal (high G^I) and low-income (high Z/Y) economy, the magnitude of the combined positive-signed b_3 and b_4 could actually overwhelm the magnitude of the negative-signed b_2 . Similarly, in such an economy, E_g could be negative. These two elasticities, which are estimated next, would be crucial in determining what happens to poverty reduction over time in a given economy.

3.2. Data, estimation and results

The data used in the present analysis are derived from the most recent World Bank global database,¹³ which yields at most 392 usable unbalanced panel observations involving some 123 countries over 1977–2007.¹⁴ Separate regression equations are estimated for the \$1.25 and \$2.50 poverty standards. Summary statistics by region for the poverty rates, income inequality (Gini coefficient) and mean income are reported in the Table A1.¹⁵ Note that the averages are non-weighted and, due to missing data, sample composition may vary over time. Hence, only the statistics for the entire sample period are reported for the various regions. Nonetheless, the respective regional sample poverty rates presented in Table A1 are strikingly close to the population-weighted values shown earlier in Table 2.

Using the above unbalanced panel data, Eq. (1) is estimated by applying three procedures: random-effects (RE), country fixed-effects (FE), and generalized method of moments (GMM).¹⁶ Following Kalwij and Verschoor (2007), various versions of the equation are estimated, with special attention paid to the regional effects. The instruments employed for the GMM estimation are shown in the notes for the respective tables reporting the regression results. These include, as in Kalwij and Verschoor, lagged values of the relevant explanatory income-related variables, population growth and regional dummy variables where appropriate. For addressing endogeneity, the Hansen J test is employed as an indicator of over-identification and appropriateness of the instruments used.¹⁷ Note that all the level variables used in the estimation are expressed in (natural) logarithm, while the growth variables are the logarithmic changes. Due its ability to control for possible endogeneity of the explanatory variables,¹⁸ the GMM results are selected as the most preferred and are reported in the text as Tables 5.1 and 5.2, for the \$1.25 and \$2.50 standards, respectively.

The regression results seem rather similar between the two poverty standards, and show that all the estimated coefficients are as expected. The estimates also suggest that any variation in the income and inequality elasticities across regions, and presumably across countries, is mainly attributable to differences in attributes. In particular, according to model (5), once the poverty function is fully specified, there are little regional differences with respect to the income elasticity, similarly to the finding in Kalwij and Verschoor (2007).¹⁹ From the results of this model in Tables 5.1 and 5.2, we can re-write the respective income and inequality elasticity (Eqs. (2) and (3)), first for the \$1.25 poverty standard, as:

$$E_y = -9.757 + 2.307 G^I + 1.333 Z/Y \quad (4)$$

$$E_g = 14.391 - 3.649 G^I - 2.754 Z/Y \quad (5)$$

And, for the \$2.50 poverty standard, we obtain

$$E_y = -8.178 + 1.902 G^I + 0.912 Z/Y \quad (6)$$

$$E_g = 5.336 - 1.155 G^I - 1.513 Z/Y \quad (7)$$

It is deducible from (Eqs. (4) and (6)) that the income elasticity (in absolute value) decreases with initial inequality, G^I , and with Z/Y . Hence, regions/countries with lower initial levels of inequality and higher incomes relative to the poverty

¹³ See World Bank (2009a, 2009b).

¹⁴ There are 320 and 392 usable observations for the \$1.25 and \$2.50 poverty standards, respectively.

¹⁵ We do not report the summary data for the growth rates because they would not be reliable, as the periods are not standardized across observations. That is, growth rates are calculated over different period lengths depending on data availability, so that their averages are not technically reliable.

¹⁶ Only the GMM results are, however, reported here. The other (FE and RE) estimates are very similar to the GMM and can be made available by the author upon request.

¹⁷ For details of the instruments employed, see the notes for the respective tables reporting the GMM regression results.

¹⁸ In particular, income and inequality may be endogenously determined.

¹⁹ The Hansen J test suggests that the instruments are generally 'valid' in all the models except for model (3). An F test furthermore indicates that one cannot reject the null hypothesis that the coefficients of the regional variables are equal when the model is fully specified, a result that is qualitatively buttressed by the virtually equal SEE and uncentered R^2 between models (4) and (5), especially in Table 5.1.

Notes: The dependent variable is the log-difference of headcount ratio (\$1.25/day); heteroscedastic robust *t*-statistics in parentheses; Hansen *J* statistic tests for over-identification of instruments (*p*-values in brackets). All regressors involving dlog Y_{it} are considered endogenous and are instrumented. All models are estimated using 2-step GMM.

^a Critical value, $\chi^2_{0.05}(1)=3.84$; instruments: $\log Y_{it-1}$ and dlogPOP_{it} .

^b Critical value, $\chi^2_{0.05}(6)=12.59$; instruments: regional dummy variables, $\log Y_{it-1}$ interacted with dummy variables and dlogPOP_{it} .

^c Critical value is $\chi^2_{0.05}(12)=21.02$; instruments: regional dummy variables, $\log Y_{it-1}$ and $\log G_{it-1}$ interacted with regional dummy variables and dlogPOP_{it} .

^d Critical value, $\chi^2_{0.05}(13)=22.36$; instruments: regional dummy variables, $\log Y_{it-1}$ and $\log G_{it-1}$ interacted with regional dummy variables, dlogPOP_{it} , $\log Y_{it-1} \times \log G_{it-1}$, $\log Y_{it-1} \times \log(Z/Y_{it-1})$ and $\log G_{it-1} \times \log G_{it-1}$.

^e Critical value, $\chi^2_{0.05}(18)=28.87$; instruments: same as listed in “d”.

line would exhibit larger poverty responsiveness to income changes. Similarly, from (Eqs. (5) and 7), we deduce that regions/countries with lower initial inequality levels or larger incomes relative to the poverty line would also possess higher values of the inequality elasticity. Conversely, low-income, high-inequality localities would have both low (absolute-valued) income and inequality elasticities.

Estimates of the income and inequality elasticities, generated from (Eqs. (4) to 7) at the \$1.25 and \$2.50 poverty levels, are reported in Table 6 for the various regions.²⁰ Since the country composition likely changes over time, the sample statistics of the sub-periods may not be reliable. We, therefore, focus on the elasticity estimates for the overall 1981–2007 period. According to the income elasticity estimates, the greatest responsiveness of poverty to income growth is exhibited by EECA, followed by LAC and MENA with similar values. EAP comes next, followed closely by SAS, while SSA has the least value. These results appear to hold for both poverty standards; however, as to be expected, the respective elasticities are lower for the \$2.50 poverty standard than for the \$1.25.

²⁰ Elasticity estimates based on the FE and RE models are similar to those of the GMM; however, they are not reported here for reasons of parsimony but can be made available by the author upon request.

Notes: Same as in Table 5.1, respectively.

The differences in income elasticity by region seem to be driven by differences in inequality, but also by disparities in income levels. For example, for both poverty standards, the highest elasticity enjoyed by the EECA is attributable to the stylized fact that the region exhibits the lowest initial inequality as well as the highest mean income. LAC's moderate elasticity is driven by high levels of both mean income and inequality, which tend to counteract one another, while MENA's moderate elasticity is attributable to modest income as well as moderate inequality. Meanwhile, EAP's and SAS's moderate-to-low elasticity (absolute) values are explained by their relatively low mean incomes and medium levels of inequality. Finally, SSA exhibits the lowest income elasticity, thanks to both its low income and high inequality.

The regional comparison of inequality elasticity estimates, also shown in Table 6, is similar between both poverty standards and mirrors the pattern observed for the income elasticity. That is, EECA exhibits the largest value, suggesting that its poverty rate is the most prone to distributional changes in income distribution, followed by LAC and MENA, then by EAP, and subsequently by SAS, with SSA displaying the least responsiveness. As in the case of the income elasticity, EECA's high value of the inequality elasticity is attributable to its low level of inequality and high income; LAC's moderate value results from its high income counteracted by high inequality, while MENA's moderate elasticity derives from modest levels of both income and inequality. EAP's and SAS's low-to-moderate values are attributable to their relatively low incomes and moderate levels of inequality. Finally, the smallest estimated value of the inequality elasticity for SSA is explained by high inequality and low mean income.

To most effectively reduce poverty, therefore, it appears that EECA, in one extreme, should be particularly concerned about rising inequality, which tends to increase poverty relatively easily. Meanwhile, in the light of its high income elasticity, modest growth should lead to relatively large poverty reductions. In the other extreme, SSA would require a larger dose of growth acceleration to reduce poverty, while worsening income distribution should generally be of less concern.

Furthermore, for each region, inequality elasticity tends to be larger than the income elasticity, suggesting that changes in income distribution, where feasible, can have relatively large effects on poverty reduction.

The above elasticity results are further elaborated in Figs. 2 and 3 for the \$1.25 poverty level.²¹ Fig. 2 graphs the (absolute-valued) income elasticity, E_y , as a function of initial inequality using Eq. (4), at the global mean income relative to the \$1.25 poverty line. Fig. 3 does likewise but for the inequality elasticity, E_g . The respective data points for the regions, as well as the global vector, are also plotted. As apparent, both E_y and E_g decrease with initial inequality, while the regional points are distributed around the respective graphs. Note that a point above (below) a graph at a given value of the Gini coefficient indicates a higher (lower) regional income relative to the poverty line. Thus, by virtue of their lower initial inequality levels, SAS, EAP and SSA would have all exhibited higher income and inequality elasticities than LAC, respectively, were it not for LAC's higher income. In the case of EECA, its higher income and inequality elasticity levels than SAS's, for instance, are explained mainly by its superior income level. In contrast, the larger EECA elasticity levels than LAC's are attributable to the former's lower level of inequality.

These regional estimates, however, confound the intra-regional heterogeneity. In the case of SSA, Fosu (2009) finds a considerable variation in both the income and inequality elasticities among countries. As the author argues, SSA countries with very high levels of inequality may require a relatively large emphasis on income distribution as a way of boosting the income elasticity via decreasing inequality. The most efficient poverty-reduction approach would, therefore, be country-specific.

Table A2 in Appendix A presents estimates of the income and inequality elasticities for all the 123 countries in the World Bank database for both the \$1.25 and \$2.50 poverty standards. These estimates are based on the latest year for which a given country has data and may, therefore, not be strictly comparable across countries. Nevertheless, we can draw some fairly general conclusions.

First, the income elasticity estimates are nearly all negative,²² suggesting that income growth would reduce poverty in practically all countries for both poverty standards. Second, nearly all the inequality elasticity estimates are positive;²³ hence, increases in inequality would, in general, raise poverty. Third, the estimated elasticities at the \$1.25 standard are, respectively, larger than those at the \$2.50 standard, as to be expected, since moving people out of poverty at the higher poverty line would require greater effort. Fourth, consistent with the above regional observations, the elasticities are generally largest for the EECA and lowest for the SSA countries. Indeed, the hitherto observed regional orderings appear to hold.²⁴ Fifth, as earlier observed above for the regions, the inequality elasticity seems to be appreciably larger than the respective income elasticity at the country level, especially for the \$1.25 poverty level; however, this outcome does not seem to hold generally at the \$2.50 standard.²⁵

We now focus on the results for the two emerging giants. China exhibits much larger income and inequality elasticities in the urban than in the rural sector. This finding holds for both poverty standards and implies that economic growth in the urban area would be more readily translated to poverty reduction, but then poverty in that sector would also be relatively susceptible to the poverty-increasing effect of rising inequality. In India, however, the reverse appears to be the case, with the income and inequality elasticities slightly larger in the rural area generally.²⁶ Finally, India's estimated elasticities are appreciably less than China's, respectively, especially for the urban sector.

3.3. Explaining poverty reduction by country, early-mid-1990s to present

A major objective of the current paper is to examine how the recent strong growth of developing countries may have been translated to human development such as poverty reduction. The above elasticity estimates for the 123 countries inform us of the expected changes in poverty in response to increasing growth in income or in inequality for the particular (latest) year for which a given elasticity estimate is provided. For current policy purposes, these estimates are the most pertinent.

To meet the above objective of explaining recent growth performance and poverty reduction, however, we need to situate the elasticity estimates in the relevant period. The income and inequality elasticities are, therefore, recomputed over the early-mid-1990s for the select global sample of 80 countries, using (Eqs. (4)–7).²⁷ The results are presented in Tables A3.1

²¹ The respective graphs for the \$2.50 poverty level are similar and are not reported here.

²² The only exception is Liberia and for the \$2.50 standard; the result is attributable to the country's low mean income that was appreciably below the poverty line.

²³ The exceptions are: Liberia, for both of the poverty standards; and Burundi, Guinea, Malawi, Mozambique, Rwanda, Tanzania and Zambia, where the mean incomes are appreciably below the \$2.50 poverty line. Note, however, that the magnitudes of these negative estimates are generally rather small.

²⁴ The few exceptions include Haiti and Nepal whose income elasticity estimates seem lower than the average for SSA.

²⁵ This difference in results between the two poverty standards is attributable to the much larger partial effect of inequality on poverty at the \$1.25 than at the \$2.50 level (compare intercepts in (Eqs. (5) and 7)) with the intercepts of (Eqs. (4) and 6).

²⁶ The only exception is the estimated inequality elasticity at the \$2.50 level, which is slightly larger for the urban sector.

²⁷ As explained earlier, the 80 countries were selected according to the following criteria: In each case, the starting date is the latest year for which there is data within 1990–1996, and the ending date is the latest year within 2000–2007. The selection criteria are designed to maximize the number of included countries while providing a reasonable degree of period standardization. Although the current method does not achieve perfect comparability across countries, it represents a reasonable attempt to explain recent poverty reduction by country for a large global sample. Given differences of year-coverage across countries, all statistics are annualized by dividing by the number of years between the end points for each country.

Notes: These are derived from the GMM estimates from Tables 5.1 and 5.2 and (Eqs. (4)–7) of the text.

Fig. 2. Income elasticity vs. initial income inequality. Notes: The square dots represent a distribution of the regional values of the elasticity about the global line. For example, the lowest income elasticity value displayed by SSA shows both a high level of initial inequality and a low ratio of mean income relative to the poverty line, compared to the respective global values. Dots above the line indicate higher income/poverty line ratios than the global averages, for given levels of initial inequality.

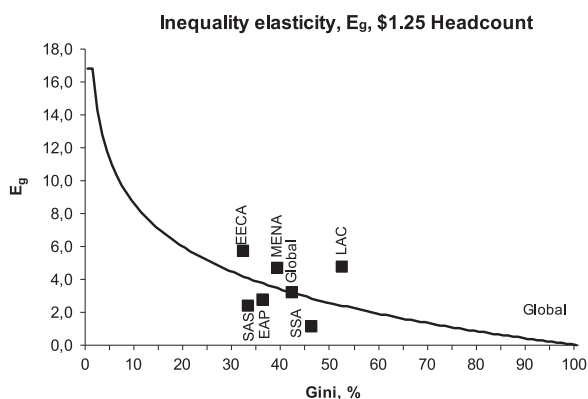

Fig. 3. Inequality elasticity vs. initial income inequality. Notes: The square dots represent a distribution of the regional values of the elasticity about the global line. For example, the lowest inequality elasticity value displayed by SSA shows both a high level of initial inequality and a low ratio of mean income relative to the poverty line, compared to the respective global values. Dots above the line indicate higher income/poverty line ratios than the global averages, for given levels of initial inequality.

and A3.2 of Appendix A, respectively, for the \$1.25 and \$2.50 standards.²⁸ Also reported are the mean annualized growths in income, inequality and poverty, for we are interested in the extent to which the observed poverty changes might be decomposable into income and inequality factors.

According to Tables A3.1 and A3.2, the income elasticity estimates are generally negative while those of the inequality elasticity are positive, as anticipated.²⁹ Hence, income increases or inequality decreases in a given country would be translated to poverty reduction over the period of the analysis: the early-mid-1990s to the present. Note from these tables also that the magnitudes of the elasticities tend to be, respectively, larger for the \$1.25 than for the \$2.50 standard, as to be expected.

To shed further light on the differential abilities of the various countries to transform economic growth to poverty reduction since the early-mid-1990s, the income and inequality elasticity estimates are ordered by country in Tables 7.1 and 7.2 for the \$1.25 and \$2.50 poverty standards, respectively. These results show that a country with a high (absolute) value of income elasticity also tends to exhibit a high value of inequality inelasticity, as already observed above for the ‘current-year’ estimates.³⁰ This is primarily because countries with large incomes (relative to the poverty line) displayed high magnitudes of both elasticities ((Eqs. (2) and 3)). The implication of the result, as earlier observed, is that lower-income countries would require greater income growth for a given expected poverty reduction; however, these countries would also need to be less concerned about inequality increases, and conversely.

4. Decomposing poverty progress into contributions by income and inequality changes

We now present in Tables 8.1 and 8.2, for the \$1.25 and \$2.50 standards, respectively, the evidence by country on the relative poverty-reduction contributions of income and inequality by country, during the early-mid-1990s to the present. For better clarity of interpretation, this reporting is done for countries exhibiting poverty declines separately from those experiencing increases in poverty.

²⁸ These are the values reported under columns A and C of Tables A3.1 and A3.2, respectively. Note that the estimates under columns B and D are illustrative only; they are indicative of the importance of initial inequality alone, with the role of income suppressed.

²⁹ For the \$1.25 standard, CAR appears as the only exception with a positive value for the income elasticity; at the \$2.50 standard, the two exceptions are CAR and Guinea. There are several exceptions for the inequality elasticity estimates, though: CAR, Guinea, Mali, Mozambique, and Swaziland for the \$1.25 standard (column C of Table A3.1); and Burkina Faso, Burundi, CAR, Guinea, Madagascar, Mali, Mozambique, Niger, Swaziland and Zambia for the \$2.50 standard (Table A3.2, column C). The main rationale for the ‘perverse’ results is that these countries had appreciably lower mean incomes than the poverty line, hence the greater preponderance of exceptions under the \$2.50 standard.

³⁰ Note that countries with the highest (absolute) values of the income elasticity are in decile 1, while those with the highest values of inequality elasticity are in decile 10. This convention is adopted in the light of the generally opposite effects of income and inequality changes on poverty. Note also that the absolute magnitudes of the elasticities could not be used here, since some countries may have the perverse opposite sign, as indicated above.

The results show that, *on average*, income growth primarily drove both poverty declines and increases. Among countries experiencing poverty reduction, income growth was responsible for practically 100 percent of the predicted poverty reduction for both poverty standards. And, in the case of countries exhibiting poverty increases, negative income growth contributed on average 74 percent and 85 percent of the predicted poverty increases for the \$1.25 and \$2.50 standards, respectively.

There are, however, major differences across countries. In many countries, improvements in the income distribution contributed further to the favorable poverty-reduction role of income growth. Brazil, for instance, experienced substantial poverty declines, thanks to the favorable changes in both income and inequality (increasing income and decreasing inequality), though a larger share emanated from income growth: 63 percent versus 37 percent for either poverty standard (Tables 8.1 and 8.2). Azerbaijan's poverty decline also resulted from both income growth and a decrease in inequality, but with the primary reduction actually coming from income distribution: 30 percent (39 percent) for income versus 70 percent (61 percent) for inequality at the \$1.25 (\$2.50) standard. Indeed, countries experiencing both favorable income and inequal-

Notes: Country categorization into deciles is based on the 'overall' income and inequality elasticities presented in Appendix Table A3.1. Growth rates are calculated using the latest observation of period 1990–1996 and the most recent 2000s value. Countries are arranged alphabetically in each decile.

ity contributions to poverty reduction include additionally (at the \$1.25 level): Cameroon, Chile, El Salvador, Ethiopia, Jordan, Nicaragua, Panama, Russian Federation, Thailand, Tunisia, Ukraine, and Venezuela.

Rising inequality, however, seems to have thwarted the poverty-reduction efforts of increasing income in many countries (see Tables 8.1 and 8.2). China's tremendous poverty decline would have been even higher without worsening inequality; the predicted fall in poverty at the \$1.25 level in the rural sector would have been 7.9 percent annually, instead of the current 6.6 percent (Table 8.1). More dramatically, rising inequality in China's urban sector reduced the rate of poverty declines by some 6.7 percentage points annually (Table 8.1). Similarly at the \$2.50 poverty level, increases in inequality considerably reduced the rates of predicted poverty reduction in both sectors of China's economy (Table 8.2).

Indeed, rising inequality led to increases in poverty overall in several countries, despite the poverty-reduction impact of income growth, such as in: Albania, Bolivia, and Cote d'Ivoire (Table 8.1). In a number of countries, however, reduced growth was responsible for rising poverty, notwithstanding increasingly favorable income distribution over time, including: Armenia, Iran, Kyrgyz Republic, Mongolia, and Yemen (Table 8.1). And, in many cases, both income levels and their distribution worsened to exacerbate the poverty picture, such as in: Argentina-urban, Djibouti, Georgia, Guinea Bissau, South Africa, and Tanzania for both poverty standards (Tables 8.1 and 8.2).

A: Predicted poverty growth by income; B: predicted poverty growth by inequality; A+B: predicted poverty growth by both income and inequality.

*Countries with perverse signs for predicted poverty (different from the observed): CAR (perverse signs for both income and inequality elasticities, with mean income < poverty line); Guinea (perverse sign for inequality elasticity, with mean income < poverty line); Mali (perverse sign for inequality elasticity, with mean income < poverty line); Swaziland (perverse sign for inequality elasticity, with mean income < poverty line); Uruguay-urban (unexplained: correct signs for elasticities, poverty should have increased); Iran (correct signs of elasticities, borderline); Lesotho (correct signs for elasticities, borderline); Colombia (correct signs for elasticities, borderline); Sri Lanka (correct signs for elasticities, borderline?); and Turkey (correct signs for the elasticities, borderline?).

5. Some country-simulation illustrations

5.1. India: linkage between GDP and income matters

As already discussed above, India's relatively modest poverty reduction since the mid-1990s resulted primarily from the modest income growth despite its substantial GDP growth. If income had grown at the same rate as (per capita) GDP of 4.8 percent annually (Table 4.1), then the (predicted) contribution of growth to poverty reduction (\$1.25 standard) would have been more than 10.0 percent,³¹ instead of less than 2.5 percent, annually (Table 8.1).

5.2. Bolivia: rising inequality hurts

Bolivia's \$1.25-level poverty rate has risen by 10.5 percent annually since the mid-1990s, despite a 1.0 percent annual income growth, thanks to a worsening income distribution (Table A3.1). Suppose income inequality had not changed. Then (predicted) poverty would have *fallen* annually by 3.2 percent instead of currently *rising* by 7.6 percent (Table 8.1).

5.3. Russian Federation: falling inequality helps

The (\$2.50-level) poverty rate of the Russian Federation fell by 12.3 percent (7.9 percent predicted) annually as of the mid-1990s, despite its meagre annual income growth rate of 0.54 percent, because its income inequality fell by 2.3 percent annually (Table A3.2). In the absence of this favorable income distribution, poverty would be predicted to fall by only 1.1 percent (Table 8.2).

³¹ That is, $4.8(-2.2) = -10.6$ for rural and $4.8(-2.1) = -10.1$ for urban.

Table 8.2

Poverty (\$2.50 Headcount ratio) growth, contribution of inequality and mean income growth to poverty reduction, early-mid-1990s–present.

Notes A: Predicted poverty growth by income; B: predicted poverty growth by inequality; A+B is predicted poverty both income and inequality.

*Countries with perverse signs for predicted poverty growth (different from the observed): Similar reasons as in Table 8.1; note that there are a few more countries with perverse elasticity signs for the \$2.50 standard due to the greater likelihood of mean income falling below the poverty line.

5.4. Burkina Faso vs. Chile: low income is a bane; high income is a boon

Burkina Faso (BF) had a lower level of inequality than Chile did (Gini coefficient of 0.51 vs. 0.55), its inequality has decreased much faster than Chile's since the mid-1990s (2.75 percent vs. 0.57 percent annually), while both countries' incomes grew equally at 1.5 percent annually (sources: Table A3.1 and World Bank, 2009a). Yet, Chile managed to reduce its (\$1.25-level) poverty by 8.2 percent annually compared with BF's of only 2.6 percent (Table A3.1). This difference is due to BF's relatively low income (\$40.8 vs. \$387.2 monthly). If BF had enjoyed the same level of income as Chile, its respective income and inequality elasticities would have been -3.82 and 6.51,³² instead of -0.79 and 0.26 (Table A3.1), with a predicted poverty decline of 23.63 percent,³³ instead of 1.94 percent (Table 8.1).

6. Summary and conclusion

The current paper has examined the poverty-reduction performance in developing countries during the more recent period of relatively rapid growth globally. Using comparable data from World Bank (2009a, 2009b), we first presented evidence on GDP growth, income growth, and poverty reduction since the 1980s for the various regions of the world: EAP, EECA, LAC, MENA, SAS and SSA. The regional evidence is provided for two periods: 1981 to mid-1990s and mid-1990s to the 'present' (the latest year for which data was available between 2000-2007), with a focus on the latter strong-growth sub-period. Also examined is a global sample of 80 countries for which available data would permit reasonably comprehensive country comparative analysis.

The paper finds that, except for EECA, poverty measured at both the \$1 (\$1.25 2005 PPP-adjusted income) per day and \$2 (\$2.50 2005 PPP-adjusted income) per day decreased for all regions during the entire 1981-2005 period. Similarly, with the exception of MENA, all regions exhibited greater poverty declines in the latter sub-period. Two regions, EECA and SSA, showed increases in poverty rates during the earlier sub-period; however, poverty has declined for all regions since the mid-1990s.

The greatest poverty reduction during 1981-2005 occurred in EAP, LAC, EECA, SAS, SSA and then MENA, in that order at the \$1.25 level; at the \$2.50 standard, the order was EAP, EECA, LAC, MENA, then SAS and SSA (about the same). Qualitatively, the observed patterns of poverty decline at the regional level appear to correspond well with the GDP growth over both sub-

³² That is, based on (Eqs. (4) and 5), respectively, $-9.757+2.307(\ln 51)+1.333 \ln(37/387.2)=-3.82$ and $14.391-3.649(\ln 51)-2.754 \ln(37/387.2)=6.51$.

³³ That is, $(-3.82)(1.5)+(6.51)(-2.75)=-23.63$.

periods. During 1981–1995, EECA and SSA experienced rising poverty rates in response to negative per capita GDP growth, while the remaining regions registered both positive GDP growth and poverty reduction.

In the latter sub-period, per capita GDP increased for all regions. Moreover, those regions experiencing higher GDP growths also exhibited greater declines in poverty. The rate at which GDP growth was translated to poverty reduction, however, differed across regions. The transformation rate was particularly low for SAS, especially at the \$2.50 standard.

As the two most populous nations and ‘emerging giants’, the performance of China and India has received special attention in the present study. While both countries have registered substantial poverty reductions since 1981, the rate of decrease is much larger for China than for India. *Income* growth in India has been rather minimal despite its substantial per-capita GDP performance. Once this phenomenon is noted, India’s relatively modest poverty reduction, especially since the mid-1990s is not unusual.

In contrast, income growth in China more closely reflects its GDP growth. Moreover, while relatively large in both sectors, the bulk of poverty decline in China was in the urban sector, rendering current poverty essentially a rural phenomenon. To a lesser degree, a similar observation holds for India, where the urban bias is observed at the \$2.50 standard; at the \$1.25 level, however, the rate of poverty reduction was actually larger in the rural than in the urban sector during the more recent period.

The study then concentrates on the global sample of 80 countries for which sufficient data were available for the early-mid-1990s to the present (2000s). We find that there is a wide range of observed relationships between income growth and poverty reduction. For the majority in the sample, income growth seemed to be a reasonable reflection of the observed poverty reduction. A number of countries, however, exhibited strong income growth but low poverty reduction, and conversely. Apparently, income inequality was a major mediating factor for these countries. Also of importance was the level of income (relative to the poverty line), which tended to increase the responsiveness of poverty reduction to both income and inequality changes. Indeed, the measure of ‘relative income–poverty transformation efficiency’ vectors presented in the current paper suggests that there is qualitatively a large cross-country variation in the transformation of economic growth to poverty reduction.

Estimating the income and inequality elasticities based on the latest year for which data were available for the 123 countries in the World Bank database, we find a large cross-country variation of responsiveness of poverty to both income and inequality growths. The elasticities were also computed for the early-mid-1990s for 80 countries with comparable data. We observe a large range of cross-country values for both elasticities. Initial income inequality differences and disparities in income levels crucially determined the responsiveness of poverty reduction to income and inequality growths in many countries. Lower-inequality and higher-income countries exhibited greater abilities to transform a given growth rate to poverty reduction. Such countries would also enjoy larger inequality elasticities, suggesting that increasing inequality would be more deleterious to poverty in these countries than in their low-income counterparts.

In particular, low-income countries would conversely require greater efforts on both income growth and decreases in inequality to reduce their poverty levels. Yet it is these countries that must urgently decrease their poverty levels. This quandary suggests not only that low-income countries must try harder internally, but also that a reasonable case can be made for external assistance.

Despite major differences in the roles of income and inequality in changes in the poverty picture since the early-mid-1990s, some generalities seem in order. First, most of the 80 countries (about 75 percent) registered poverty reduction. Second, *on average*, nearly all of this success could be attributable to income growth rather than inequality changes. Third, among the countries experiencing rising poverty rates, most of this record was, *on average*, due to income declines: 74 percent (85 percent) to income versus 26 percent (15 percent) to inequality for the \$1.25 (\$2.50) standard.

The above ‘average’ results are in concert with previous studies that extol the dominant virtues of growth based on the effects of growth on income quintiles (e.g., Dollar and Kraay, 2002). While analytically appealing, however, this growth-dominant story is inadequate, for we have also documented herein major differences across countries globally. In some sense, our findings are consistent with Ravallion’s (2001) that looking beyond the averages can uncover country-specific differences in what happens to inequality during growth. We have gone a step further, however, by estimating the implications of such differences for poverty reduction by region and for a large number of countries.

The current results suggest that adopting the appropriate pro-poor growth strategies requires some understanding of idiosyncratic country attributes.³⁴ After all, policies are by and large country-specific, and the present study does indeed find that there are substantial differences in the abilities of countries to translate economic growth to poverty reduction, based on their respective inequality and income profiles. By shedding light on this transformation process by country these findings, at least, provide a ‘road-map’ for undertaking country studies to uncover the underpinning idiosyncratic factors. Understanding such country-specific profiles is crucial in crafting policies for most effectively achieving poverty reduction globally.

Appendix A

See Appendix Tables A1–A3.2.

³⁴ There is a large volume of the literature on pro-poor poverty; for a recent review, see Grimm et al. (2007).

Notes A: Overall income elasticity, B: Income elasticity attributable to initial inequality; C: Overall inequality elasticity, D: Inequality elasticity attributable to initial inequality; E: Annualized (log-difference) growth of mean income; F: Annualized (log-difference) growth of inequality; G: Annualized (log-difference) growth of the poverty rate. For each country the latest year in 1990–1996 is used as the start-year and the most recent year with data in the 2000s as the end-year; details in text. Note that for Belarus, Estonia and Latvia, the latest \$1.25 headcount ratio value is 0 and has been replaced with 0.001 in order to compute the growth rates (source provides data for .01 in some cases). Income and inequality elasticity estimates are derived from (Eqs. (4) and 5) of the text, respectively, using country 1990–96 mean values for the initial Gini coefficient, G^1 , and for the poverty line relative to income, Z/Y .

Table A3.2

Income and inequality elasticities vs. poverty reduction since the *early-mid-1990s*, for the 80 countries, \$2.50 poverty standard.

Notes: A: Overall income elasticity, B: Income elasticity attributable to initial inequality; C: Overall inequality elasticity, D: Inequality elasticity attributable to initial inequality; E: Annualized (log-difference) growth of mean income; F: Annualized (log-difference) growth of inequality; G: Annualized (log-difference) growth of the poverty rate. For each country the latest year in 1990–1996 is used as the start-year and the most recent year with data in the 2000s as the end-year; details in text. Note that for Belarus, Estonia and Latvia, the latest \$1.25 headcount ratio value is 0 and has been replaced with 0.001 in order to compute the growth rates (source provides data for 0.01 in some cases). Income and inequality elasticity estimates are derived from (Eqs. (6) and 7) of the text, respectively, using country 1990–1996 mean values for the initial Gini coefficient, G^1 , and for the poverty line relative to income, Z/Y .
